Floating Rate Notes Valuation and Risk

FinPricing
Summary

- Floating Rate Note (FRN) or Floating Rate Bond
- Introduction
- The Use of Floating Rate Notes
- Valuation
- Practical Guide
- A Real World Example
A floating rate note (FRN), also called floating rate bond, is a bond in which the investor will receive coupons paid by the issuer at a floating coupon equivalent to a money market reference rate, such as LIBOR or federal fund rate plus a spread at specified dates before bond maturity.

The bond principal will be returned at maturity date.

Almost all FRNs have quarterly coupons.

FRNs are usually issued by corporations, federal agencies, municipalities and states/provinces to finance a variety of projects and activities.
The Use of Floating Rate Notes

▪ A FRN carry little interest rate risk as its duration is close to zero due to periodic reset.

▪ The price of a FRN has very low sensitivity to changes in interest rates because the floating coupon increases but the discounting also increases as interest rate rises.

▪ An investor who wants conservative investments may choose floating rate bonds.

▪ FRNs become more popular when interest rates are expected to increase.

▪ A FRN carry lower yield than fixed rate bonds of the same maturity.

▪ FRNs have unpredictable coupon payments.
Valuation

- The present value of a FRN is given by

\[ V(t) = \sum_{i=1}^{n} F_i \tau_i P e^{-(r_i+s)T_i} + P e^{-(r_n+s)T_n} \]

where

- \( t \) – valuation date
- \( i \) – \( i \)th cash flow from 1 to \( n \)
- \( r_i \) – continuous compounded interest rate for the period \((t, T_i)\)
- \( T_i \) – coupon payment date of the \( i \)th cash flow
- \( s \) – credit spread
- \( P \) – principal amount or face value
- \( \tau_i = \tau(T_{i-1}, T_i) \) – accrual period \((T_{i-1}, T_i)\) of the \( i \)th cash flow.
- \( F_i = F(t; T_{i-1}, T_i) = \left( \frac{D_{i-1}}{D_i} \right) / \tau_i \) - simply compounded forward rate
- \( D_i = D(t, T_i) \) – discount factor
The present value of a bond computed by any pricing models is the dirty price of the bond. To purchase a bond, the buyer pays this dirty price.

Although investors pay dirty prices, bonds are typically quoted in terms of clean prices.

Dirty Price = Clean Price + Accrued Interest

Intuitively, \( e^{-(r+s)T} \) can be regarded as a credit risk adjusted discount factor.

To use the model, one should first calibrate the model price to the market quoted price by solving the credit spread. Comparing to curve construction or calibration for exotic products, the solving here is very simple.
After making the model price equal to the market price, one can calculate sensitivities by shocking interest rate curve and credit spread.

We use LIBOR curve plus credit spread rather than bond specific curves for discounting because bond specific curves rarely exist in the market, especially issued by small entities. Using LIBOR curve plus credit spread not only accounts for credit/issuer risk but also solves the missing data issue.

Usually the forecasting curve is different from the discounting curve. For instance, the forecasting curve is the treasury curve but the discounting curve is the LIBOR curve plus credit spread.
